

The data of **2 patients with unresponsive wakefulness syndrome** is provided (P1 and P2). For each patient there are **2 sessions** (e.g., recording days) during which the vibro-tactile paradigm (VTP) was performed **twice** respectively. This results in 8 files during which patients either achieved a “**low**” or “**high**” classification accuracy. The classification in this case is a two-class problem: non-target (1) vs. target (2). However, there is a 3rd class as well which is the distractor (-1). This is a little vibrator which is mounted to the leg of the patient which vibrated much more often than the non-target and target as you can see in the Figure below. As the name suggests the distractor is only there to distract the patient.
